

Group 66 Scoping Document

Event planner: Hokie Plans

Project Name: Hokie Plans

What we are building:

Our group is building an event tracking app. Users will be able to add events as they come up, and include helpful details about the event, such as the date and time, location, and type of event (birthday, work party, etc). Users will be able to see all the events they have through a request, and events will be displayed in chronological order. Users will also be able to delete and edit events if needed.

Our MVP:

Our group's MVP (Minimum Viable Product) is a local app that runs off a program that can take in multiple events, each with their own unique attributes like time of the event, date of the event, and location of the event, and then organize those events in order of time.

Our stretch goals:

Our group's main stretch goal is to give the user a feature where, based on the type of event they have entered, a helpful list of what to bring will be provided upon request. For example, if a user has a birthday party as an event, when requested, they'll get a list of things to bring, including a card and a gift. We strive to add many different lists for different types of events.

Bad Inputs

The bad inputs the code could possibly take are an invalid date; an example would be 33/FEB/21. The reason it would be invalid is that there are not 33 days in a month, so it would not be valid. Also, another bad input would be people entering "DD/MM/YY" instead of "DD/MM/YYYY".

What we can't do yet:

We don't know how to sort by date and time yet, and the different sorting algorithms that could be used for different date formats (8/31/2026 vs August 31st, 2026). We also don't know how to check if dates are formatted correctly or how to ask the user to enter the date. We also don't know how many classes we need, and if we'll need a dictionary to organize events.
